E1iz@b3ths_D1g1t@_N0t3b00k_2

This week's class helped me find my footing within the course and imagine my own relationship to programming more broadly; rather than letting ourselves be intimidated by the inaccessibility of programming language and the mystification of computer work by weirdo techbros, we can encourage ourselves by embracing a process of exploration and fun. By taking the end product off of its pedestal and working together, we are empowered to learn.

Admin notes:

- can learn more about particular programming processes through library
- can get certified in digital history through the library program + montreal/queens/etc programs - talk to Shawn for more details

Course content:

- Serendipity and playfulness as an adaptive information-seeking and sharing stradegy, as one way of doing things
- Kim Martin and Anabelle Quan-Hass ask: where does serendipity come from/arise in your work as historians/digital historians in digital spaces?
    - Twitter used to be a place of serendipitous encounters... a virtual third space of people interested in digital work. Super important for ways of being exposed to different methods
    - networks broke when twitter became the X hellscape
        - bluesky is a twitter clone, but an isolated bubble. It's supposed to be a way of communicating across different servers, but in reality doesn't do this. Macadon is better
          A platform that fosters serendipity:
          -> must be trigger-rich
          -> must enable connections
          -> surfaces interesting things/people that you might not otherwise encounter while watching what you're doing
          -> should foster exploration and lead to the unexpected
          consider: Where do our thoughts come from about certain kinds of digital history work being better than others?

Infrastructure....

- Historic England's vanishing archive
    - the website was streaming the images rather than providing them directly

    - now everything is broken on the Historic England digital archive, and all of the citation links to are thereby now defunct
- Alan Liu on critical infrastructure studies:
    - we can't build things by breaking them
    - objects composed as infrastructure through social, epistemological, ontological relations that become visible when things break
    - places of digital preservation for collections...dropped images and their metadata into a database that lives on someone's computer so that they can be digitally accessible
        - but who pays for that server that is connected to the internet? who keeps the lights on?
        - a budget for a project isn't busy work and isn't fantasy but it is a statement of where the value is
            - Brendon Walsh: "spatial rhetorics"... the ways things set up to be maneuvered also impacts relations, learning, what can be accomplished. The way an institution itself constitutes a kind of pedagogy
                - where does the infrastructure of our own research push us?
                    - For example, Great Lakes Research Alliance trying to build infrastructure that benefits data sharing among Indigenous nations
                    - Does the infrastructure we use limit us, or does it allow us to have conversations and try new things?
                    So... digital history is can be enriched by serendipity. Look for platforms that foster as the platforms we use do have an impact on what is possible
- digital history a kaleidoscope of meanings/issues/possibilities
- computational history about finding the answer
- Travellersim Redux square gives us a sense of the kinds of digital history that we might do
- question, if we use the same data and the same model.. will we get the same result?
    - reproduction: when you do the same method on the same data, do we get the same result? Then that means the study replicated and we have increased the value of the original study and its insights
    - replication: same approach, different data set... means replicable
    - robust: same data, different approach
    - generalizable: diff method, diff data but same conclusion
    in history we don't use the above.. we don't often try regoing at the same history with same method or same data or same whatever... we try to do something totally new everytime. Not much of a culture of reuse
    - but we could do that.. and we could do it playfully~!!
        - issue of data being hoarded, and we spend so much money trying to recreate

        - sshrc trying to incentivize the sharing of data
    - open notebook project: sharing data as you work on a project
        - of course, we not all in good relation for data to be shared
        - power dynamics/choices in what gets shared

A lot of digital history is mucking around and there is noone to tell you you're right or wrong... but many ways to see if reproducible, replicable, robust, and/or generalizable
- paradata is the keeping track, where we can find the serendipity and the sharing

Digital history primary imagines a world where you are working directly in python... which is not fun to install so....
https://colab.research.google.com/drive/1vDBuWS1lHh5Snm8cGHF3GAKHRW7h8S77?usp=sharing
a notebook interface on top of python

Playing with the terminal!!!

- My mac os has its origins in unichs - a tool for each action, which would be chained together so output of one tool is input of the other. This is mac under the hood, which we access through terminal
- mac vs windows.. user interfaces abstract the very different processes/ textual languages beneath the surface

1. Command Line Murderers
    1. on my mac, right clip file and "New Terminal Tab at Folder"
    2. will open up with my username, mystery, and percentage
       Last login: Thu Oct 1 12:53:17 on ttys000
       elizabethspence@dhcp-98-202 clmystery-master %
       -> apple doesn't show the path of folders the way microsoft does...
    3. we are now in... THE TERMINAL!!! We want to be in powershell
    4. through commands here, we can open files and read mystery notes
    5. on mac, command "ls"
       -> elizabethspence@dhcp-98-202 clmystery-master % ls
       opens up
       crimescene interviews memberships people streets vehicles
    6. lizabethspence@dhcp-98-202 clmystery-master % cat instructions
    - opens up the mystery

Nanocheatsheet

The command line (also known as the command line interface, or CLI, or sometimes the terminal), is a plain text-based i$

You have a prompt, and you can type in a command and hit 'Enter' to execute it. An example command would be:
touch newfile.txt
This command will create a file called `newfile.txt`.
How to access the command line
Mac OS X: Go to /Applications/Utilities and click on "Terminal" or search for "Terminal" in Spotlight.

---

7. elizabethspence@dhcp-98-202 clmystery-master % cd mystery -> THIS IS TO GO TO THE MYSTERY DIRECTORY!
8. elizabethspence@dhcp-98-202 mystery % ls -> THIS IS TO LOOK INSIDE IT
9. then look for clues with grep clue command "elizabethspence@dhcp-98-202 mystery % grep "CLUE" crimescene"
10. cd .. is what takes you back
11. dir on mac = gives you the path of where you are!

process of demystification of asshole programmers

darwin letters.

1. csplit darwin1
   = loops pattern of searching for darwin1 and puts them into another folder
2. csplit darwin2 does same with darwin2

NEVER DO RM-RF
mkdir is make directory
touch makes an empty note files

Repdoducibility, replicability, robiustness, gerneralizability so important. Because things get lost. notes allow us to recreate the things that get lost

Make sure you do tutorial next week so we can all help Gwen!!
